AppleTalk Management Information Base

Status of this Memo

This memo defines objects for managing AppleTalk objects for use with the SNMP protocol. This memo is a product of the AppleTalk-IP Working Group of the Internet Engineering Task Force (IETF). This RFC specifies an IAB standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "IAB Official Protocol Standards" for the standardization state and status of this protocol. Distribution of this memo is unlimited.

1. Abstract

This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP-based internets. In particular, it defines objects for managing AppleTalk networks.
2. The Network Management Framework

The Internet-standard Network Management Framework consists of three components. They are:

- **RFC 1155** which defines the SMI, the mechanisms used for describing and naming objects for the purpose of management. **RFC 1212** defines a more concise description mechanism, which is wholly consistent with the SMI.

- **RFC 1156** which defines MIB-I, the core set of managed objects for the Internet suite of protocols. **RFC 1213**, defines MIB-II, an evolution of MIB-I based on implementation experience and new operational requirements.

- **RFC 1157** which defines the SNMP, the protocol used for network access to managed objects.

The Framework permits new objects to be defined for the purpose of experimentation and evaluation.

3. Objects

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. Objects in the MIB are defined using the subset of Abstract Syntax Notation One (ASN.1) [7] defined in the SMI. In particular, each object has a name, a syntax, and an encoding. The name is an object identifier, an administratively assigned name, which specifies an object type. The object type together with an object instance serves to uniquely identify a specific instantiation of the object. For human convenience, we often use a textual string, termed the OBJECT DESCRIPTOR, to also refer to the object type.

The syntax of an object type defines the abstract data structure corresponding to that object type. The ASN.1 language is used for this purpose. However, the SMI [3] purposely restricts the ASN.1 constructs which may be used. These restrictions are explicitly made for simplicity.

The encoding of an object type is simply how that object type is represented using the object type’s syntax. Implicitly tied to the notion of an object type’s syntax and encoding is how the object type is represented when being transmitted on the network.

The SMI specifies the use of the basic encoding rules of ASN.1 [8], subject to the additional requirements imposed by the SNMP.
3.1. Format of Definitions

Section 5 contains the specification of all object types contained in this MIB module. The object types are defined using the conventions defined in the SMI, as amended by the extensions specified in [9,10].

4. Overview

AppleTalk is a protocol suite which features an open peer-to-peer architecture that runs over a variety of transmission media. AppleTalk is defined in [10]. This protocol suite interoperates with the IP protocol suite through various encapsulation methods. As large AppleTalk networks are built that coexist with large IP networks, a method to manage the AppleTalk networks with SNMP becomes necessary. This MIB defines managed objects to be used for managing AppleTalk networks.

4.1. Structure of MIB

The objects are arranged into the following groups:
- LLAP
- AARP
- ATPort
- DDP
- RTMP
- KIP
- ZIP
- NBP
- ATEcho

These groups are the basic unit of conformance. If the semantics of a group is applicable to an implementation, then it must implement all objects in that group. For example, a managed agent must implement the KIP group if and only if it implements the KIP protocol.

These groups are defined to provide a means of assigning object identifiers, and to provide a method for managed agents to know which objects they must implement.

4.2. The LocalTalk Link Access Protocol Group

The LocalTalk Link Access Protocol (LLAP) is a medium-speed data-link protocol designed for low cost and plug-and-play operation. The LLAP group is designed to manage all interfaces on a managed device that use this protocol.
4.3. The AppleTalk Address Resolution Protocol Group

The AppleTalk Address Resolution Protocol (AARP) is used to map between AppleTalk node addresses, used by the Datagram Delivery Protocol, and the addresses of the underlying data link layer. The AARP table allows for management of the Address Mapping Table on the managed device.

4.4. The AppleTalk Port Group

An AppleTalk Port is a logical connection to a network over which AppleTalk packets can be transmitted. This group allows the management of the configuration of these AppleTalk ports.

4.5. The Datagram Delivery Protocol Group

The Datagram Delivery Protocol (DDP) is the network-layer protocol that is responsible for the socket-to-socket delivery of datagrams over the AppleTalk Internet. This group manages the DDP layer on the managed device.

4.6. The Routing Table Maintenance Protocol Group

The Routing Table Maintenance Protocol (RTMP) is used by AppleTalk routers to create and maintain the routing tables that dictate the process of forwarding datagrams on the AppleTalk internet. The RTMP group manages the RTMP protocol as well as the routing tables generated by this protocol.

4.7. The Kinetics Internet Protocol Group

The Kinetics Internet Protocol (KIP) is a protocol for encapsulating and routing AppleTalk datagrams over an IP internet. This name is historical. The KIP group manages the KIP routing protocol as well as the routing tables generated by this protocol.

4.8. The Zone Information Protocol Group

The Zone Information Protocol (ZIP) is used to maintain a mapping between networks and zone names to facilitate the name lookup process performed by the Name Binding Protocol. The ZIP group manages this protocol and the mapping it produces.

4.9. The Name Binding Protocol Group

The Name Binding Protocol (NBP) is a transport-level protocol that is used to convert human readable service names into the numeric AppleTalk network addresses needed for communicating across the
AppleTalk network. The NBP group manages this protocol and the NBP services that exist on the managed device.

4.10. The AppleTalk Echo Protocol Group

The AppleTalk Echo Protocol is a transport-level protocol used to test and verify the status of the AppleTalk internet. The AtEcho group manages this protocol.

4.11. Textual Conventions

A new data type is introduced as a textual convention in this MIB document. This textual convention enhances the readability of the specification and can ease comparison with other specifications if appropriate. It should be noted that the introduction of this textual convention has no effect on either the syntax or the semantics of any managed objects. The use of this is merely an artifact of the explanatory method used. Objects defined in terms of this method are always encoded by means of the rules that define the primitive type. Hence, no changes to the SMI or the SNMP are necessary to accommodate this textual convention which is adopted merely for the convenience of readers and writers in pursuit of the elusive goal of clear, concise, and unambiguous MIB documents.

The new data type is:

\[
\text{DdpAddress ::=} \quad \text{-- 2 octets of net number,} \\
\text{-- 1 octet of node number} \\
\text{OCTET STRING (SIZE (3))}
\]

-- The ZIP Group

zipTable OBJECT-TYPE
SYNTAX SEQUENCE OF ZipEntry
ACCESS not-accessible
STATUS mandatory
DESCRIPTION
"The table of zone information for reachable
AppleTalk networks."
::= { zip 1 }

zipEntry OBJECT-TYPE
SYNTAX ZipEntry
ACCESS not-accessible
STATUS mandatory
DESCRIPTION
"An entry of zone information for a particular
zone and network combination."
INDEX { zipZoneNetStart, zipZoneIndex }
::= { zipTable 1 }

ZipEntry ::= SEQUENCE {
  zipZoneName    OCTET STRING,
  zipZoneIndex   INTEGER,
  zipZoneNetStart OCTET STRING (SIZE(2)),
  zipZoneNetEnd  OCTET STRING (SIZE(2)),
  zipZoneState   INTEGER
}
zipZoneName OBJECT-TYPE
SYNTAX OCTET STRING
ACCESS read-write
STATUS mandatory
DESCRIPTION
"The ASCII zone name of this entry."
 ::= { zipEntry 1 }

zipZoneIndex OBJECT-TYPE
SYNTAX INTEGER
ACCESS read-only
STATUS mandatory
DESCRIPTION
"An integer that is unique to the zipZoneName that is present in this entry. For any given zone name, every zipEntry that has an equal zone name will have the same zipZoneIndex."
 ::= { zipEntry 2 }

zipZoneNetStart OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(2))
ACCESS read-write
STATUS mandatory
DESCRIPTION
"The network that starts the range for this entry. This address is a two octet DDP network address in network byte order."
 ::= { zipEntry 3 }

zipZoneNetEnd OBJECT-TYPE
SYNTAX OCTET STRING (SIZE(2))
ACCESS read-write
STATUS mandatory
DESCRIPTION
"The network that ends the range for this entry. This address is a two octet DDP network address in network byte order. If the network to which this zip entry pertains is a Phase 1 network or a non-extended network, the value for zipZoneNetEnd shall be two bytes of zero."
 ::= { zipEntry 4 }

zipZoneState OBJECT-TYPE
SYNTAX INTEGER {
    valid(1),
    invalid(2)
}
ACCESS read-write
STATUS mandatory
DESCRIPTION
"The state of this zip entry.

Setting this object to the value invalid(2) has
the effect of invalidating the corresponding
entry in the zipTable. That is, it effectively
disassociates the mapping identified with said
entry. It is an implementation-specific matter
as to whether the agent removes an invalidated
entry from the table.
Accordingly, management stations must be
prepared to receive from agents tabular
information corresponding to entries not
currently in use. Proper interpretation of
such entries requires examination of the
relevant zipZoneState object."

::= { zipEntry 5 }

-- The NBP Group

nbpTable OBJECT-TYPE
SYNTAX SEQUENCE OF NbpEntry
ACCESS not-accessible
STATUS mandatory
DESCRIPTION
"The table of NBP services registered on this
entity."
::= { nbp 1 }

nbpEntry OBJECT-TYPE
SYNTAX NbpEntry
ACCESS not-accessible
STATUS mandatory
DESCRIPTION
"The description of an NBP service registered on
this entity."
INDEX { nbpIndex }
::= { nbpTable 1 }

NbpEntry ::= SEQUENCE {
    nbpIndex       INTEGER,
    nbpObject      OCTET STRING,
    nbpType        OCTET STRING,
    nbpZone        OCTET STRING,
    nbpState       INTEGER
}
nbpIndex OBJECT-TYPE
  SYNTAX INTEGER
  ACCESS read-only
  STATUS mandatory
  DESCRIPTION
    "The index of this NBP entry. This value ranges
    from 1 to the number of NBP entries currently
    registered on this entity."
  ::= { nbpEntry 1 }

nbpObject OBJECT-TYPE
  SYNTAX OCTET STRING
  ACCESS read-write
  STATUS mandatory
  DESCRIPTION
    "The name of the service described by this
    entity."
  ::= { nbpEntry 2 }

nbpType OBJECT-TYPE
  SYNTAX OCTET STRING
  ACCESS read-write
  STATUS mandatory
  DESCRIPTION
    "The type of the service described by this
    entity."
  ::= { nbpEntry 3 }

nbpZone OBJECT-TYPE
  SYNTAX OCTET STRING
  ACCESS read-write
  STATUS mandatory
  DESCRIPTION
    "The zone the service described by this entity is
    registered in."
  ::= { nbpEntry 4 }

nbpState OBJECT-TYPE
  SYNTAX INTEGER {
    valid(1),
    invalid(2)
  }
  ACCESS read-write
  STATUS mandatory
  DESCRIPTION
    "The state of this NBP entry.

    Setting this object to the value invalid(2) has
the effect of invalidating the corresponding entry in the nbpTable. That is, it effectively disassociates the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive from agents tabular information corresponding to entries not currently in use. Proper interpretation of such entries requires examination of the relevant nbpState object.

::= { nbpEntry 5 }

-- The ATEcho Group

atechoRequests OBJECT-TYPE
SYNTAX Counter
ACCESS read-only
STATUS mandatory
DESCRIPTION "The number of AppleTalk echo requests received."
::= { atecho 1 }

atechoReplies OBJECT-TYPE
SYNTAX Counter
ACCESS read-only
STATUS mandatory
DESCRIPTION "The number of AppleTalk echo replies sent."
::= { atecho 2 }

END
